

Above is an initial rendition of an interactive ArcGIS dashboard that will model some of the elements to be provided at the end of this project. The user will have:

- the feature layer of California fire events in the map element
- a table that will show the variables of interest from the data analysis models (month, year, event duration, maximum / minimum / mean daily growth rates per event)
- a pie chart that will show the percentage of each land cover type

The audience / user will be able to customize what geographic range the table and pie chart adapt to; using either a single fire event polygon by clicking directly on the map or by utilizing the lasso, rectangle, etc. to encompass multiple fire event polygons to be interpreted. This will help the target audience of forest landowners and managers to choose only the fire events that would fall within their property, understanding how the prior fire event growth rates and land cover types could impact their needs for proactive management.

Team Task List / Responsibilities / Next Analytical Steps

- Revise / select the most robust ANOVA models to use for insight to dashboard final project (team member 1 responsible, review/edit by team member 2 and 3)
- Decide how to incorporate the results from ANOVA models into the dashboard product, start drafting dashboard (team member 2 responsible, review/edit by team member 1 and 3)
- Refining draft of final dashboard product, ensuring that the target audience interaction is meaningful and accessible (team member 3 responsible, review/edit by team member 1 and 2)
